# SoCe

**Why?**

**SoCe**  XILINX

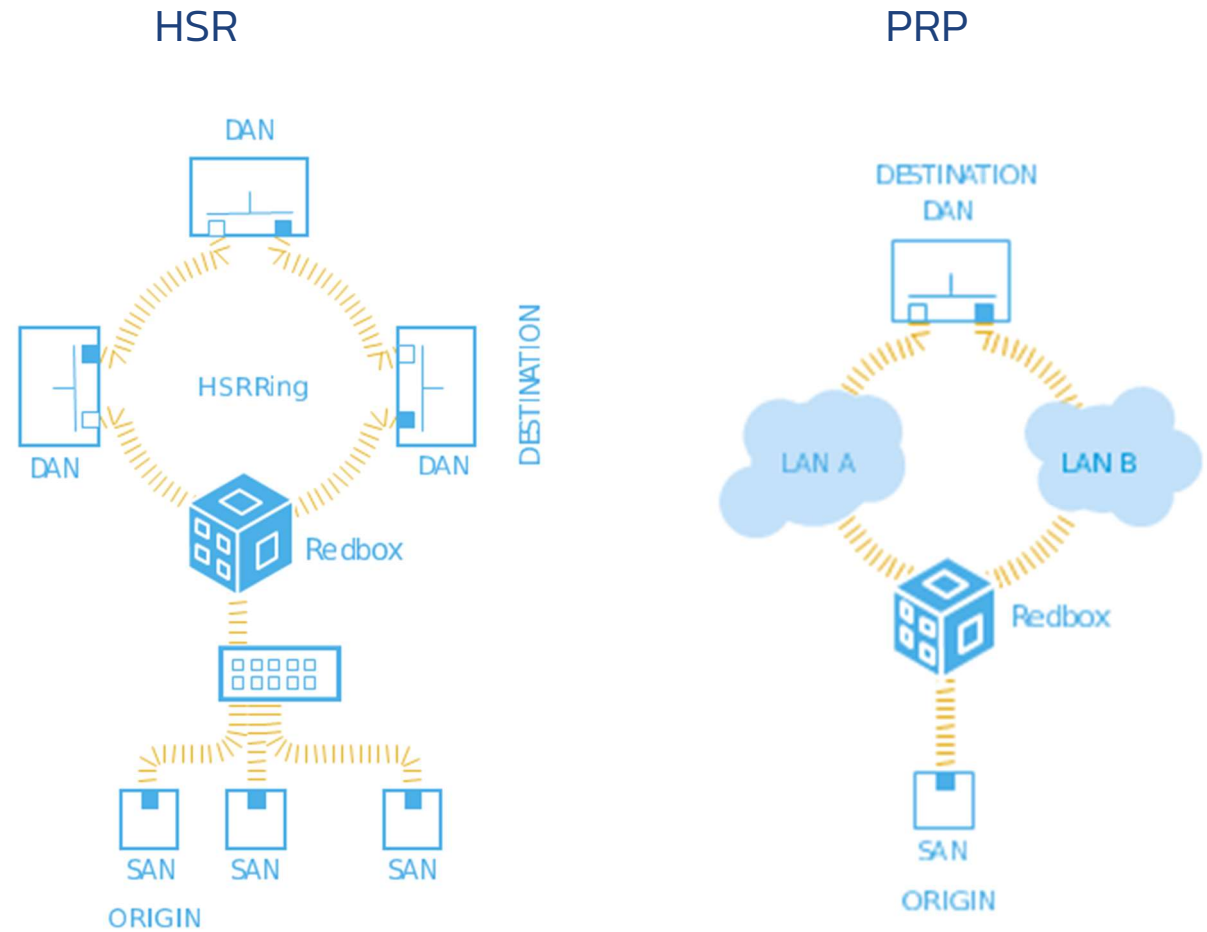

## Critical Systems: Where “availability” is a must

- No-frame lost
- Zero-delay recovery time

## Current State-of-the-Art: HSR/PRP

- IEC 62349
- Widely extended in the Electric Sector: IEC 61850
- Industry, Military and Broadcasting

## Current State-of-the-Art: HSR/PRP

- Pros:
  1. Robust Layer-2 operation (hardware)
  2. No configuration required
  3. PRP operated in standard Ethernet networks (x2)
  4. IEEE 1588v2 supported
- Cons:
  1. HSR needs HSR-capable devices in the ring
  2. Limited applicability for real-time operation:
    - > HSR supports the calculation of the Worst-case delivery time

# SoCe

## What?

SoCe  XILINX

# Practical Reason for FRER with 802.1CB

## Factory Floor Example – simplified

- 1000 connected nodes
- 1 Ethernet frame per millisecond in average from each node
  - »  $1000 \text{ nodes} \times 1000 \text{ frames}/(\text{s} \times \text{node}) \times 10^5 \text{ s/day} = 10^{10} \text{ frames/day}$
- Assume a probability for a frame that it's lost/damaged of  $5 \times 10^{-5}$
- Change into safe state after two consecutive damaged packets with  $(5 \times 10^{-5})^2 = 2.5 \times 10^{-11}$ 
  - » **1 product line stop per month** ( $= 10^{10} \times 2.5 \times 10^{-11}$ )

**Factory Automation for Production require  
availability enhancements through Redundancy**

---

# 802.1CB and TSN Network Elements

- TSN 802.1CB distinguishes
  - » **Talker End System / Listener End System:** Two MAC Interfaces without no switching between them. Typically one port is active, the other is passive to react on media (cable) failures.
  - » **Relay system:** Bridge or router. Placed in ring or chain topologies

Devices Under Test (DUT) in this presentation are  
End Systems with built-in Relay Systems (2 external ports)

# Redundancy (802.1CB)

## Principle

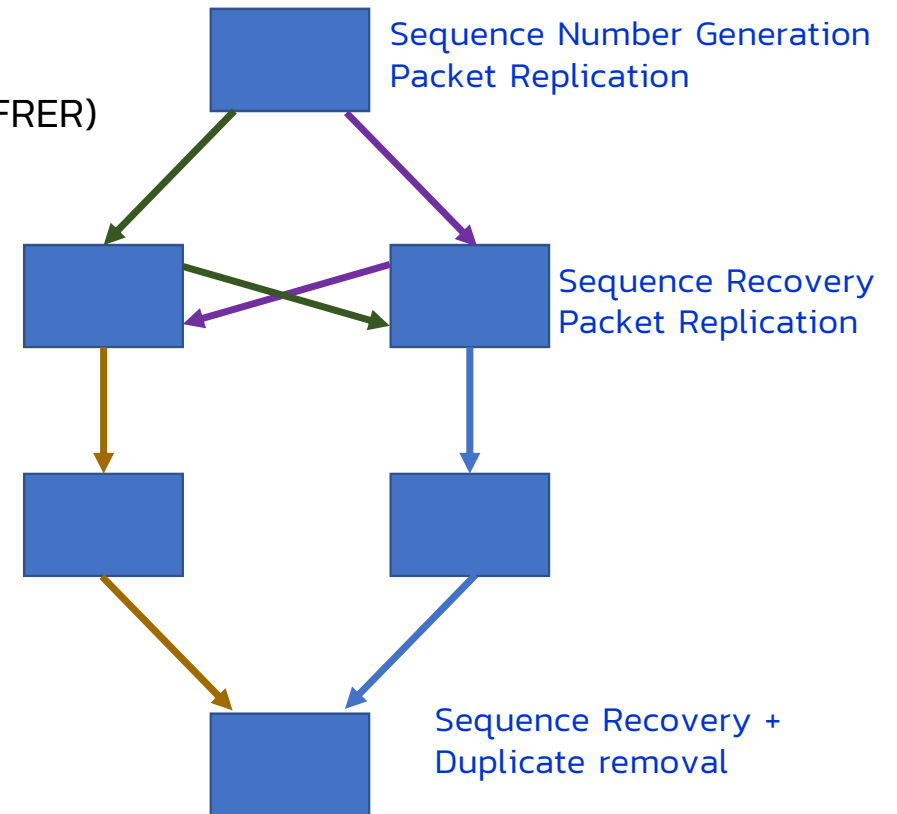

- Frame Replication and Elimination for Reliability (FRER)

## Targets

- Higher availability
- Robustness against equipment failures

## Functions

1. Stream Identification
2. Replication of Frames
3. Redundancy Tag generation with Frame Sequence Number
4. Identification and removal of Duplicates
5. Sequence Recovery

# The Redundancy TAG

Sequence Encode/Decode Function in 802.1CB, are needed to identify the sequence in a split stream and compund stream

» Mandatory feature: Redundancy Tag (or R-TAG) in frames with EtherType "F1C1"

Figure 7-4—R-TAG format

» Optional feature in CB: HSR Sequence Tags and PRP Sequence Trailers

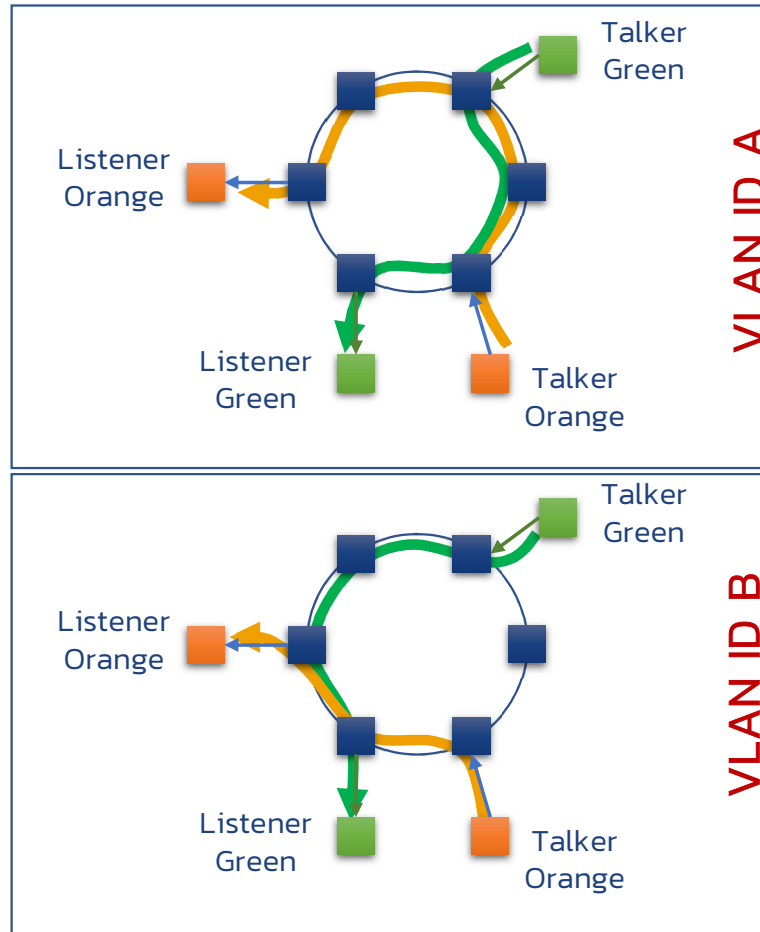

> 802.1CB-compliant coding of HSR and PRP tags not supported yet by test equipment

# FRER: Frame Replication and Elimination for Reliability

## Specification Overview

Two split streams form a compound stream

- Same DMAC Address for a Listener
- Different VLAN ID for redundant flows
- Individual forwarding rules for each split stream
- The Redundancy Tag (R-TAG) defines the sequence of frames

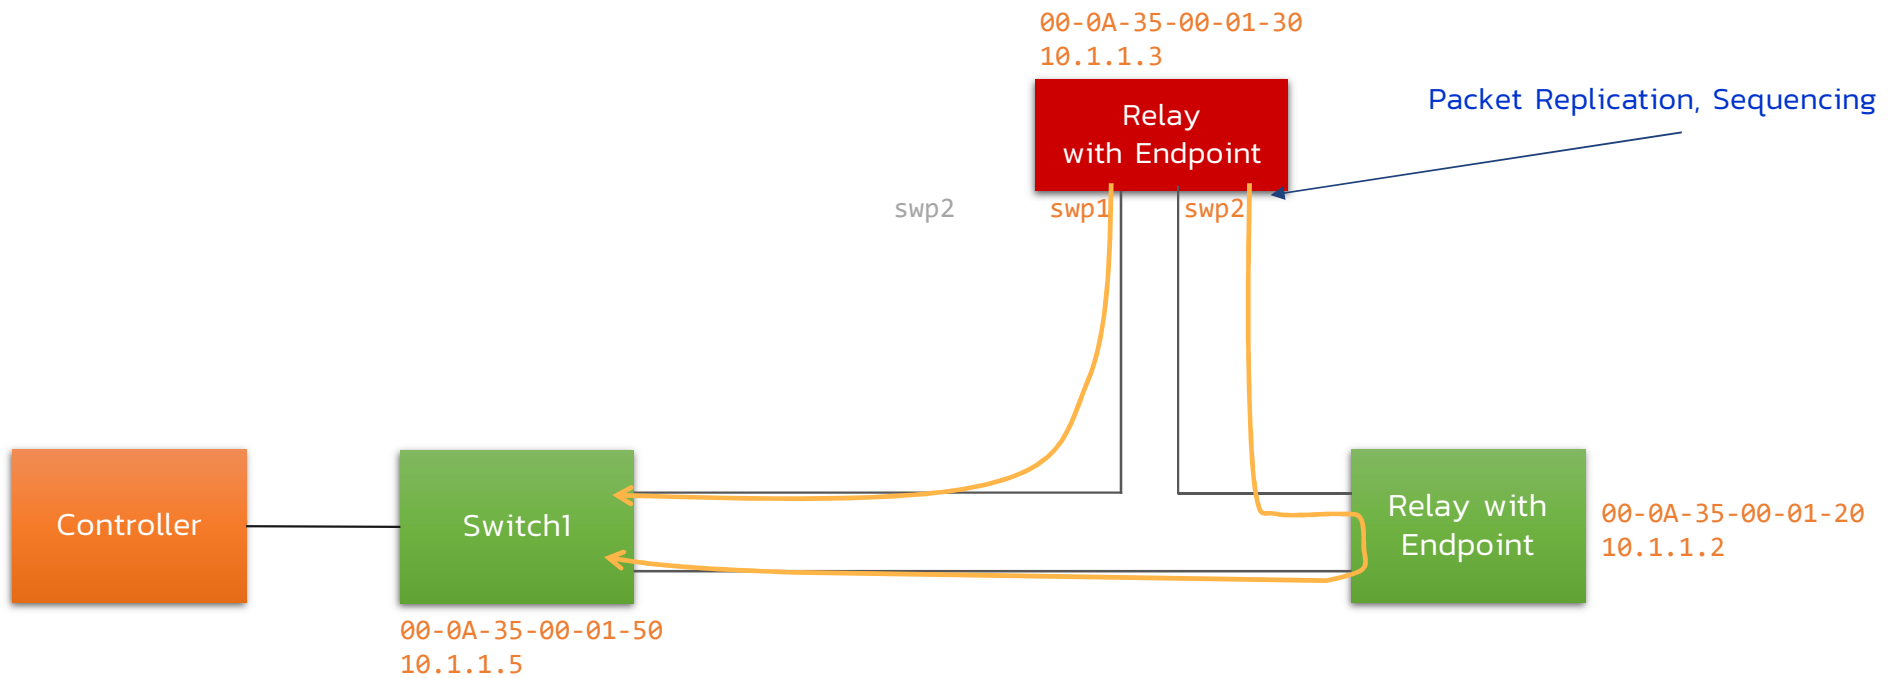

## Implementation

Stream Identification in each node

FRER Member Memory

- Identifies which split stream belong to a compound stream
- Specifies physical port over which a split stream is accepted
- Configures sequence recovery behavior

- Functional description:
  - » Talkers:
    - > RELY-CPPS sensor connected to ONA Milling Machine
    - > Xilinx Eval Board connected to video camera
  - » Listener:
    - > GATE40 connected to control PC

# CFAA TSB CB Pilot – Starting considerations

- Functional description:
  - » Talkers:
    - > GATE40 connected to control PC
  - » Listener:
    - > RELY-CPPS sensor connected to ONA Milling Machine

# CFAA TSB CB Pilot – Starting considerations

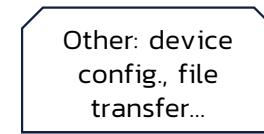

- Traffic classification
  - » Sensor/CNC information: Scheduled traffic. VLAN A, PCP A.
  - » Real-time video stream: Reserved traffic. VLAN B, PCP B.
  - » Injected traffic and general traffic: Best-effort traffic. VLAN C, PCP C.

PCP A -Scheduled

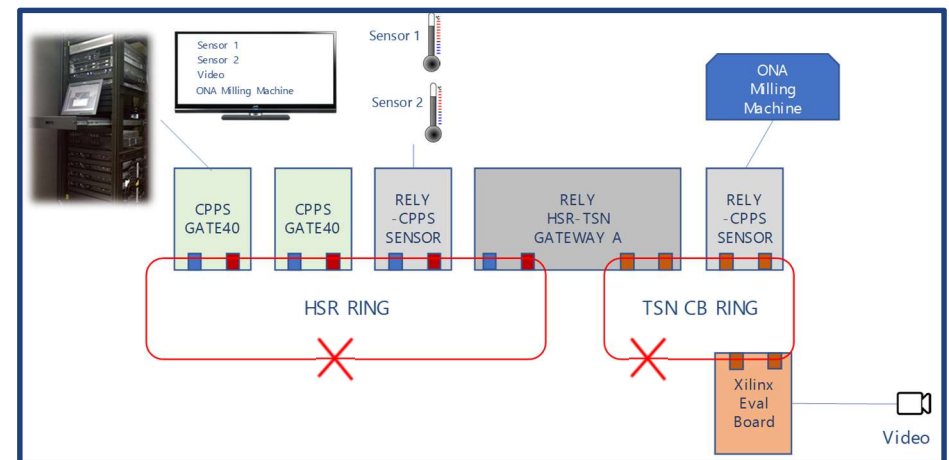

PCP B - Reserved

PCP C – Best effort

# CFAA TSB CB Pilot – Target

- Network failure behaviour on different situations:
  1. HSR Ko, TSN Ok
  2. HSR Ok, TSN Ko
  3. HSR Ko, TSN Ko

Check no packet loss / Holdover recovery = 0

---

## CFAA TSB CB Pilot – Test constraints

- Traffic classification: use of VLANs in HSR
- Merge *non time-sensitive* network (HSR) and *time-sensitive* network (TSN)
  - » No time control in the transmission for transferring HSR to TSN (Qbv)
  - » Buffer overflow causes packet loss
- Decoupled IEEE 802.1CB testing required
  - » RESULTS: No packet loss

---

## CFAA TSB CB Pilot – To Do

1. Latencies and data bandwidth measurements
2. Explore other mode-of-failure
3. Set-up extension to avoid Single-point-of-Failure

---

## Summary

- Current high-availability Ethernet solutions lack full determinism support
- IEEE 802.1CB fulfils the technical requirements of critical sectors
- In the CFAA pilot, it has been tested:
  - » The use of CB Yang models for configuration
  - » The interoperability between two TSN technology providers
  - » The simultaneous operation of HSR and TSN rings

# About SoC-e

- » Provides IP cores, modules and end-equipment for
  - > Networking:
    - > Deterministic Ethernet:
      - > MTSN, D-HSR
    - > High-availability Ethernet:
      - > HSR/PRP, MRP, S-HSR
    - > Time-aware Ethernet:
      - > MES, UES, Field-buses
  - > Synchronization:
    - > IEEE1588, IRIG-B
  - > Real-time Cyber-security

# About SoC-e

Time Sensitive Networking (TSN) is key for industrial applications such as process and machine control where low communication latency and minimal jitter are critical to meeting closed loop control requirements. TSN is the first fully open, standard and interoperable way to fulfill these requirements.
